INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.*
- Write your answers in capital letters using black ink or you may type them.*
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.*
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.*
- Once you have filled in the form you must remember to sign and date it.*
- For details of the fee and ways to pay please contact the Patent Office.*

Devices for blending materials and bags for use in such devices

This invention relates to devices for blending materials and bags for use in
5 such devices. The materials to be mixed or blended may be liquids or
semi-liquid matter, and in some cases solids, powders or even gases. The
invention is particularly concerned with the preparation of samples for
bacteriological or chemical testing.

10 There are existing blending devices comprising a door which acts as a support
for holding a sample bag and two reciprocating paddles for acting on the bag.
A bag may be placed on the support and then brought into an operating
position (by closing the door of the device) to clamp in position and seal the
bag. The paddles are arranged to reciprocate, alternately pressing on the outer
15 surface of the bag, kneading the contents of the bag to achieve a blending
action. The paddles reciprocate over a fixed range of motion and the support
can be positioned so that there is always an appropriate gap in which the bag
may sit during blending. The minimum gap between the paddles and the
support during blending can be termed the "paddle clearance".

20

During the time that blending devices of the type described above have been

on the market, techniques for analysing samples in the fields of bacteriological and chemical testing have improved. As a result of these improvements scientists now often work with smaller samples.

- 5 In general, when working with smaller samples, a smaller paddle clearance is required. Otherwise, the paddles either fail to make contact with the bag or make insufficient contact to achieve effective blending of the contents of the bag. The result of this is that smaller samples may remain unblended.
- 10 When working with smaller samples there is also a problem in obtaining a useful blended sample. For example, a conventional bag sold for use with a blending device marketed by the applicants is designed to hold between 5ml and 80 ml of liquids - with such sized samples, good results are achieved. However, it has been found that if 250 μ l of liquid is used in this conventional
- 15 bag, the result can be that you merely end up with the inside of the bag becoming wet. It can be difficult or impossible to extract a useful sample of the liquid.
- 20 It is an object of the present invention to alleviate at least some of the problems associated with the prior art.

According to a first aspect of the present invention there is provided a device for blending materials comprising a carrier support arranged to support a closed bag containing material to be blended, at least one reciprocating kneading paddle having an extended position and being arranged to apply a kneading
5 action to the walls of a supported bag for homogenising its contents, and adjustment means for controllably varying a spacing between the paddle when in its extended position and the carrier support.

Such an arrangement can facilitate the blending of differently sized samples.

10 Thus, for example a device can be used for blending conventional 5ml to 80ml samples and for much smaller samples. Moreover the provision of adjustment means, means that it is a simple matter for a user to change the spacing between the paddle and carrier support (change the paddle clearance) for different sized samples.

15

Typically, the adjustment means comprises a user operable control for use in varying the spacing. The user operable control may comprise a knob which is rotatable by the user to vary the spacing.

20 Preferably the adjustment means is arranged so that the spacing may be varied during operation of the device. This means that the process of blending a

sample may be begun and the pressure exerted on the bag, and sample, changed during the blending process.

Preferably the adjustment means comprises a cam arrangement for varying the
5 spacing between the extended paddle position and the carrier support.

Because of the continual operation of the paddles when the device is in use and the forces exerted between the paddles and the carrier support, the adjustment mechanism needs to be robust. For this reason a cam arrangement is favoured
10 over use of a lead screw or some other threaded component, which is more likely to wear or jam over time.

The cam arrangement may comprise a pair of interacting cam portions whose cam surfaces face one another. A first of the cam portions may be mounted
15 against rotation in the device and a second of the cam portions may be mounted in the device for rotation relative to the first cam portion. The cam portions may be arranged so that relative rotation of the pair of cam portions causes a spacing between their respective mounting points to change.

20 The second cam portion may be rotatable by rotation of the user operable control.

The device may comprise a backing portion on which the carrier support is mounted. The carrier support may be arranged for movement relative to the backing portion to change the spacing between the paddle when in its extended position and the carrier support. One of the cam portions may be mounted on the carrier support and the other of the cam portions may be mounted on the backing portion such that relative rotation of the cam portions causes the spacing between the carrier support and the backing portion to change, thus changing the spacing between the paddle when in its extended position and the carrier support.

10

Preferably the device comprises a door which comprises the backing portion, the carrier support and the adjustment means. The backing portion may comprise the outer surface of the door. The user operable control may be provided at the outer surface of the door.

15

Where the user operable control is a knob this may be mounted to the second cam portion and protrude through the backing portion. Thus in the case where the backing portion comprises the outer surface of the door, the knob for adjusting the paddle clearance may be provided on the door.

20

According to a second aspect of the present invention there is provided a sample bag comprising a generally triangular sample holding portion.

5 The generally triangular shape of the sample holding portion allows easier collection of the sample after blending. When the blending process is complete, a user may grasp the bag and, using his thumb and forefinger (or otherwise), drag the dispersed sample to an apex of the triangle. Once the sample has been collected in an apex of the triangle, a pipette tip may be inserted into the bag to collect the sample from the corner. This method results in minimal loss of
10 sample.

Here what is important is that there is a collecting zone for the sample. Thus the expression generally triangular should be interpreted broadly, for example, the triangle could have curved sides.

15

According to another aspect of the present invention there is provided a sample bag comprising a sample holding portion that comprises a sample collecting portion. The sample collecting portion should preferably be small compared to the size of the bag.

20

The sample bag may comprise a pair of generally rectangular sheets which may

be sealed together by a pair of seal lines to form the generally triangular sample holding portion.

There may be further seal lines between the pair of sheets, although often such additional lines will serve no useful function.

One or more seal line may be applied to a generally rectangular bag to form the triangular sample holding portion.

The sample bag may be a paddle blender sample bag.

According to a third aspect of the present invention there is provided a method of preparing a sample comprising the steps of:

placing material in a sample bag comprising a generally triangular sample holding portion;
blending the material; and
extracting a sample from the bag by squeezing the bag to cause at least some of the contents to collect in an apex of the generally triangular sample holding portion and extracting the collected contents from the apex of the sample holding portion.

According to a fourth aspect of the invention there is provided apparatus comprising a device according to the first aspect of the present invention and a bag according to the second aspect of the present invention wherein the width of the bag is substantially the same as the width of a paddle in the device which is arranged to contact the bag for blending of the contents.

Throughout this specification the word "comprise", or variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated element, integer or step, or group of elements, integers or steps, but not the exclusion of any other element, integer or step, or group of elements, integers or steps.

A blending device and a bag for use therewith which embody the present invention are now described, by way of example only, with reference to the accompanying drawings in which:

Figure 1 is a simplified schematic side view of a blending device being loaded;

Figure 2 is a simplified schematic side view of the blending device shown in

Figure 1 when loaded;

Figure 3 is a simplified sectional view of the blending device shown in Figures 1 and 2 which shows paddles and a drive mechanism of the device;

Figure 4 shows a door of the device of Figures 1 to 3 in more detail, partly in section, and with the carrier support in a withdrawn position;

Figure 5 shows the door shown in Figure 4 but with the carrier support in an extended position;

Figure 6 is a plan view of one of the cam portions included in an adjustment mechanism of the device shown in Figures 1 to 5; and

Figure 7 shows a sample bag that, amongst other things, may be used in the blending device shown in Figures 1 to 5.

15

Figures 1 to 3 show basic features of a blending device in schematic form only and details of the device embodying the invention have been omitted from these Figures for the sake of clarity.

20

At this basic level the device comprises a door 1 which is pivotable about a

hinge provided at one end and comprises a carrier support 2 for supporting a bag 3 containing a sample to be blended. Clamping sealing means 4 is provided to hold the bag 3 and to provide a seal prior to and during operation of the device.

5

In this embodiment a kneading means which comprises a first and second paddles 5,6 is provided. The first paddle 5 has an associated driving means 8 for reciprocatingly driving the first paddle 5 in a direction which is substantially perpendicular to the kneading surface 5a of the first paddle 5.

10 Similarly, a second driving means 9 is provided for reciprocatingly driving the second paddle 6 in a direction which is substantially perpendicular to a kneading surface 6a of the second paddle 6. A common motor 10 provides the power for both of the driving means 8, 9 which are each in the form of transmission gearing arrangements.

15

The door 1 is pivotable about the hinge between an open position in which a sample bag 3 can be loaded (see Figure 1) and a closed position in which a sample bag is brought into contact with the clamping sealing means 4, so sealing the bag 3 (see Figure 2). Further in the closed position, the bag 3 and
20 the material contained therein are brought into contact with the kneading surfaces of the first and second paddles 5, 6.

Figure 3 shows the paddles 5, 6 in line at an equal distance from the carrier support 2. In use the paddles 5, 6 are driven out of phase. Thus operation of the machine, starting from the configuration shown in Figure 3, will cause one paddle 5 to move towards the support 2, and one paddle 6 to tend to move
5 away from the support 2. At the extremes of the reciprocating motion, the paddle nearest to the support 2 will be separated from the support 2 by a paddle clearance.

The reciprocation of the paddles 5, 6 tends to crush the sample in the bag 3
10 and to push the sample around the bag 3 causing the sample to be blended.

There are various different configurations of paddles that may be used in such devices and different drive patterns that may be used. Thus, for example there may be a single paddle, or each paddle may be rectangular or specially
15 shaped to encourage circulation of the contents, there may be more than two paddles, paddles may be driven in phase, island baffles may be provided between paddles and so on.

In the present embodiment an important feature is the facility for adjusting the
20 paddle clearance. In the present embodiment this adjustment facility is provided by a mechanism provided in the door 1, details of which are omitted from

Figures 1 to 3 but which are shown in Figures 4 to 6.

Figures 4 and 5 show a section through the door 1 to make the adjustment mechanism visible. The section is taken to one side of the adjustment mechanism such that the adjustment mechanism is shown in elevation rather than section. The door 1 comprises an outer plate 10 within which is mounted the carrier support 2. When the door 1 is moved in to the closed position (corresponding to the position in Figure 2), the outer plate 10 engages with a main casing of the blending device (not shown) and the support 2, bag 3 and paddles 5,6 are enclosed.

The carrier support 2 is arranged for movement relative to the outer plate 10 of the door via operation of a cam arrangement 11. It will be seen that movement of the carrier support 2 towards and away from the outer plate 10 of the door causes the paddle clearance A to change. Figure 4 shows the carrier support 2 in a withdrawn position (maximum paddle clearance) and Figure 5 shows the carrier support 2 in an extended position (minimum paddle clearance).

The cam arrangement 11 comprises an outer cam portion 111 and an inner cam portion 112 which are provided with their respective cam surfaces facing one another and retained in contact with one another.

The inner cam portion 112 is mounted to the carrier support 2 on a surface which is opposite that which is for supporting an inserted bag 3. The inner cam portion 112 is fixed against rotation.

5 The outer cam portion 111 is mounted in a cam portion housing 113. The housing 113 comprises a knob 113a, which projects through an aperture formed in the outer plate 110 of the door 1. The cam portion housing 113 is mounted for rotation relative to the outer plate 110 of the door 1 and the outer cam portion 111 is mounted so as to rotate with the cam portion housing 113.

10

Thus the outer cam portion 111 is arranged for rotation relative to the inner cam portion 112. Furthermore the cam surfaces on the two cam portions 111, 112 are arranged so that relative rotation between the cam portions 111, 112 from a start position causes the cam portions 111, 112 to be driven apart.

15

Therefore, rotation of the knob 113a by a user causes the carrier support 2 to move relative to the outer plate 10 of the door and hence changes the paddle clearance. It should be noted that the paddle clearance may be adjusted from the exterior of the device - i.e. by operation of the knob 113a and that the
20 paddle clearance can be adjusted during operation of the device if required. Furthermore, within the range of adjustment provided, the paddle clearance

may be varied continuously.

Figure 6 shows a plan view of the cam surface of the inner cam portion 111. In this embodiment the cam surfaces of the two portions 111,112 are substantially
5 the same.

However, to give cam adjustment it will be clear that all that is required is the provision of interacting surfaces which allow a user to change the separation between components by movement of these surfaces relative to one another.

10 Thus the movement might be linear rather than rotary and there may be a single cam portion and an appropriate following portion. However rotary movement is preferred, as is the provision of a pair of interacting cam portions. Even in such a case the cam portions need not have the same or similar cam surfaces, they merely need to interact to give the desired separation effect.

15

The surface of the inner cam portion 111 comprises a flat circular portion 111a having no camming function and a rim portion 111b. The rim portion 111b varies in height around the circumference of the inner cam portion 111 reaching five peaks 111c to form a saw tooth like profile (the side of the rim
20 portion 111b can be seen in Figures 4 and 5). Progressing clockwise around the rim 111b of the inner cam portion 111, the rim 111b ramps up to a peak 111c

before dropping sharply and then ramping up to the next peak.

It will be appreciated that differing numbers of peaks and differing cam profiles may be chosen to give different effects. It has in fact been found that the use of three ramp like portions with three respective peaks is particularly effective. Although not shown in the drawings, in the present embodiment stop means are provided to prevent a user turning the knob such that the cam surfaces jump of the end of respective peaks causing a collapse of the carrier support towards the outer plate of the door 1. The stop position can be chosen to keep a desired minimum zone of contact between the facing cam surfaces.

With the carrier support 2 in the withdrawn position, shown in Figure 4, the profiled surfaces of the inner and outer cam portions 111, 112 are substantially aligned so that there is near complete contact. In this configuration the carrier support 2 is positioned as far away from the paddles 5, 6 as the blending device will permit with the door 1 closed.

With the carrier support in the extended position, shown in Figure 5, the profiled surfaces of the inner and outer cam portions 111, 112 are substantially out of line and the surfaces are only in partial contact. In this configuration the carrier support 2 is disposed as near to the paddles 5, 6 as the blending device

will permit with the door 1 closed.

Alternative embodiments may be constructed so that when the carrier support 2 is in the extended position there is effectively a zero paddle clearance, allowing the user to select as small a clearance as desired. Further, of course the paddle clearance may be adjusted in use.

Many different types of sample bags may be used with devices of the general type described above.

10

Figure 7 shows a preferred type of bag 3 for processing small samples. The bag 3 is formed of two pieces of rectangular plastic which are sealed together. A first seal line 3a across a short edge of the rectangular plastic sheets forms a sealed end of the bag 3. Two additional seal lines 3b and 3c originate from a point (in this embodiment - the centre) on the first seal line 3a and are inclined away from one another to form a triangular receiving portion 30 into which material may be placed. The open edge 31 of the triangular receiving portion 30 is shorter than the other two sides 32 and 33, which are of equal length. The receiving portion 30 has an apex 34 which acts as a collecting zone located adjacent to the seal line 3a at the closed end of the bag 3.

20

When the bag 3 is placed in a blending device of the type described above and the door 1 is closed, the clamping sealing means 4 seals the receiving portion 30.

5 A sample may be readily inserted into the bag 3 via the open edge 31. The sample may then be blended using the blending device as described above. After blending has been completed a user may grasp the bag 3 and, using his thumb and forefinger (or otherwise) drag the dispersed sample to the apex 34 of the receiving portion 30. Once the sample has been collected in the apex 34,
10 a pipette tip may be inserted into the receiving portion 30 to collect the sample from the apex 34. This method results in minimal loss of sample.

It will be seen that other generally triangular shaped receiving portions may be provided to similar effect - for example there may be curved seal lines.

15

Besides the seal lines mentioned above there may be other seal lines between sheets of plastic making up the bag. One or more seal line may be added to a conventional rectangular sample bag to give the desired receiving portion 30. In such a case a single diagonal sealing line could provide a triangular receiving
20 portion with one of the existing edges of the bag giving the other edge of the receiving portion.

The bag may be dimensioned so as to closely match the size of the kneading surface 5a,6a of one of the paddles 5,6 of the blending device. Where the kneading surface 5a,6a is rectangular, this rectangle may be of the same size and shape as that of the sample bag.
